Modern laser architecture

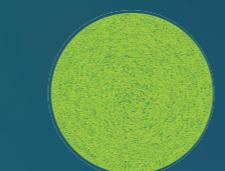

μ-CHIP
Technology

Innovative μ-chip technology

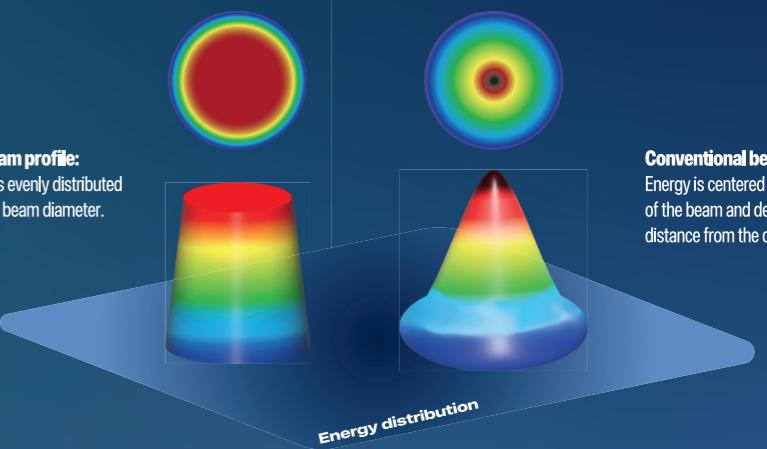

→ Homogeneity:

Homogeneous energy distribution across the 400 µm beam diameter ensures uniform, seamless treatment.

Homogeneous
400 µm
CITO laser spot

CITO 532 Beam profile:
Laser energy is evenly distributed over the entire beam diameter.

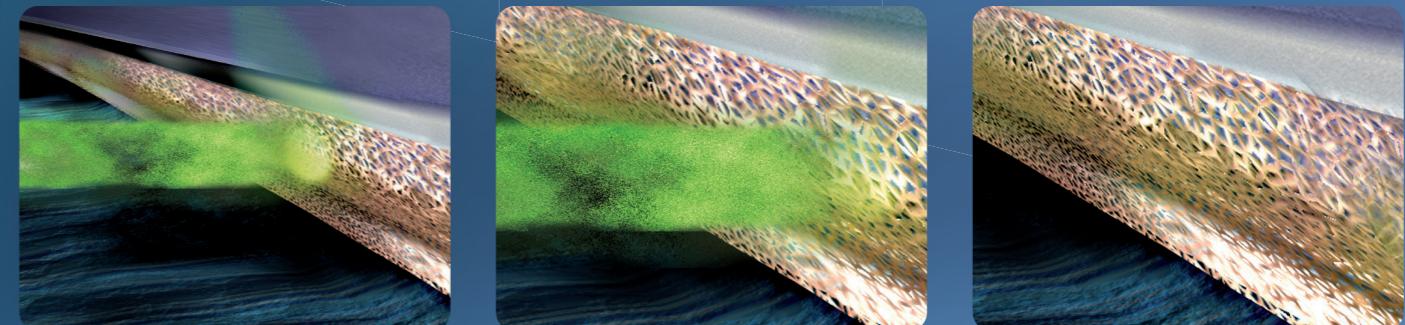

→ Reproducibility:

Energy stability from pulse to pulse over the entire duration of treatment makes SLT particularly predictable, as energy fluctuations are avoided.

→ Speed:

With the world's fastest repetition rate of up to 10 Hz, you can reduce treatment times to a minimum and increase treatment comfort.

Selective laser trabeculoplasty (SLT) for open-angle glaucoma

The energy of the green laser (532 nm) is applied in short, defined laser pulses (4 ns) homogeneously distributed over a 400 µm beam diameter in the trabecular meshwork, where it is selectively absorbed by the pigmented cells. This recruits macrophages, which remove cell debris and extracellular melanin from the trabecular meshwork. In addition, macrophages stimulate the release of cytokines which, among other things, increase the permeability of the endothelial layers of the trabecular meshwork and Schlemm's canal and ensure better drainage of the aqueous humor. As this process causes neither structural nor thermal damage, SLT is repeatable.
